Wet snow

Persistent weak layer

Increase in danger of wet avalanches in the course of the day.

The early morning will see favourable conditions over a wide area. Individual avalanche prone locations for dry avalanches are to be found on extremely steep shady slopes and at transitions from a shallow to a deep snowpack. In many places there is a danger of falling on the hard snow surface.

As the day progresses small and medium-sized wet avalanches are possible. In places where the outgoing longwave radiation during the night is reduced the danger will increase earlier. Avalanche prone locations are to be found in particular on east, south and west facing slopes below approximately 2400 m and on north facing slopes below approximately 2000 m. Moist and wet avalanches can in isolated cases be released in near-surface layers by people. Individual gliding avalanches can also occur. Backcountry tours should be concluded timely.

Snowpack

Danger patterns

dp.10: springtime scenario

Outgoing longwave radiation during the night will be quite good over a wide area. In the northeast a partly overcast night. As a consequence of falling temperatures the snowpack will consolidate. Above the tree line the snowpack will soften later than the day before. Below the tree line the snowpack will only just freeze. Here the snowpack will soften rapidly.

Over a wide area strong foehn wind from the north. The wind will transport only a little snow.

Isolated avalanche prone weak layers exist in the snowpack at high altitudes and in high Alpine regions, especially on near-ridge shady slopes, as well as at transitions from a shallow to a deep snowpack in high Alpine regions.

Tendency

As the day progresses on steep sunny slopes there will be an increase in the danger of wet avalanches.
